Bandwidth

- A bandwidth metric would choose a higher-bandwidth path over a lower-bandwidth link. However, bandwidth by itself still may not be a good metric. What if one or both of the T1 links are heavily loaded with other traffic and the 56K link is lightly loaded? Or what if the higher-bandwidth link also has a higher delay?

Load

- This metric reflects the amount of traffic utilizing the links along the path. The best path is the one with the lowest load.

Delay

- Delay* is a measure of the time a packet takes to traverse a route. A routing protocol using delay as a metric would choose the path with the least delay as the best path. There may be many ways to measure delay. Delay may take into account not only the delay of the links along the route but also such factors as router latency and queuing delay. On the other hand, the delay of a route may be not measured at all; it may be a sum of static quantities defined for each interface along the path. Each individual delay quantity would be an estimate based on the type of link to which the interface is connected.

Reliability

- Reliability* measures the likelihood that the link will fail in some way and can be either variable or fixed. Examples of variable-reliability metrics are the number of times a link has failed or the number of errors it has received within a certain time period. Fixed-reliability metrics are based on known qualities of a link as determined by the network administrator. The path with highest reliability would be selected as best.
