Computational Fluid Dynamics in Drinking Water Treatment Bas Wols, 2011-10-20 Special Offer KWR Drinking Water Treatment Set Buy all five books together and save 119 Computational Fluid Dynamics CFD uses advanced numerical models to predict flow mixing and bio chemical reactions In drinking water engineering CFD is increasingly applied to predict the performance of treatment installations and to optimise these installations A lack of understanding of the hydraulics in drinking water treatment systems has resulted in suboptimal design of installations The formation of unwanted disinfection by products and the energy consumption or use of chemicals is therefore higher than necessary The aim of this work is to better understand the hydraulic and bio chemical processes in drinking water treatment installations using experimental and numerical techniques By combining these techniques CFD modelling is further developed as a tool to evaluate the performance of these installations This leads to new insights in the applicability of models in ozone and UV systems and new insights in design concepts of these systems CFD modelling proves to be a powerful tool to understand the hydrodynamic and bio chemical processes in drinking water systems If applied properly accounting for the complex turbulent motions and validated by experiments this tool leads to a better design of UV reactors ozone systems and other systems dictated by hydraulics

OPTIMIZATION OF DISSOLVED AIR FLOTATION FOR DRINKING WATER TREATMENT THROUGH CFD MODELING. Babak Lakghomi,2015 The dissolved air flotation DAF process is known for its efficiency in the removal of low density particles from water The performance of the system depends in part on the hydrodynamics of the flow Whereas experimental flow measurement methods for DAF can be very challenging due to the presence of bubbles and particles computational fluid dynamics CFD can be applied as an alternative approach for improving the understanding of the hydrodynamics but would still require validation In this study two phase and three phase analytical and CFD models of DAF were developed to evaluate the formation of stratified flow back and forth horizontal flow layers in the separation zone and its impact on bubble and particle removal By including the effects of bubble aggregation and bubble particle aggregation the models were able to predict the formation of stratified flow under different air fractions bubble sizes and loading rates The CFD model showed that stratified flow improved bubble removal as well as particle removal demonstrating that up to 130% higher loading rates can be achieved in the presence of stratified flow An increase in air fraction and bubble size was shown to improve bubble removal but particle removal began to decrease when air fractions and bubble sizes increased beyond optimum levels The CFD model was then validated with a pilot scale DAF system by comparing measurements of residence time distribution RTD bubble layer position and bubble particle contact efficiency In general the CFD model was able to represent the pilot scale DAF flow at different loading rates with very good accuracy R2 values higher than 0.75 Finally the validated model was applied to evaluate the effect of the addition of different configurations of baffles in the separation zone The results suggested that baffles in the separation zone can enhance stratification of the flow and allow up to 86% higher loading rates
