Instructions are represented with binary digital data. In fact, the CPU makes a decision about whether it is interpreting instructions or data. This is called the stored program concept. Earlier, it was not known for the first time that the program that each device used to be built into the unit as part of the machine. One of the design flexibilities in early computers was to design the unit so that they could be reprogrammed. A breakthrough came with the realization that the program could be coded and stored in memory. If the control unit could extract the program from memory, decode the instructions, and execute them, the program could be changed manually by the computer's memory and forwarded to the unit. This stored program concept has become the standard method of building a machine designed to perform a particular task.
