

Chemical Bonds Study Guide

Introduction

Chemical bonds are the forces that hold atoms together in a molecule or compound. Understanding chemical bonding is essential to understanding the behavior of matter in various fields of science. In this study guide, we will cover the different types of chemical bonds and their characteristics.

Types of Chemical Bonds

Covalent Bonds

Covalent bonds occur when atoms share one or more pairs of electrons. The sharing of electrons allows each atom to fill its outermost energy level and become more stable. Covalent bonds can be polar or nonpolar, depending on the electronegativity difference between the atoms.

Ionic Bonds

Ionic bonds occur when one or more electrons are transferred from one atom to another, resulting in the formation of charged ions. The attraction between the opposite charges holds the ions together in a crystal lattice structure.

Metallic Bonds

Metallic bonds occur when metal atoms release their valence electrons to a common pool of electrons. This shared electron sea holds the metal cations together in a crystal structure, which can move freely through the lattice, allowing for electrical conductivity and malleability.

Bonding Theories

Valence Shell Electron Pair

Valence shell electron pair theory (VSEPR) predicts the arrangement of electron pairs in molecules and ions. It is based on the idea that electron pairs will repel each other and will arrange themselves to minimize this repulsion.

Molecular Orbital

Molecular orbital theory (MOT) describes the chemical bonding in molecules. It provides a more detailed view of the bonding process, taking into account the arrangement of the electron pairs.
