Cells and Culture Thomas Noll, 2010-07-17 Regeneration of tissue to replace damaged or injured tissue is the goal of tissue engineering Biomaterials like polyglycolic acid collagen and small intestinal submucosa provide a temporary scaffold to guide new tissue growth and organization Typically they need to be biodegradable showing good cell attachment and proliferation and they should possess appropriate mechanical properties Kim et al 2000 Synthetic polymers fulfill most of these requirements but lack cell adhesion peptides on their surface to enhance cell attachment Cell adhesion peptides are present in ECM proteins like collagen and elastin Thus a synthetic polymer coated with ECM proteins would result in a scaffold that mimics the natural cellular environment with enhanced cell attachment and proliferation The new bioactive scaffold will be made by combining a

synthetic polymer coated with a layer of recombinant ECM proteins produced by CHO cells The first step consists of identifying polymers that give best results in terms of CHO cell attachment and growth Classical techniques to determine biomass are inappropriate to evaluate 3 D structures Thus a screening system based on stable GFP expressing CHO cells was used to compare the different scaffolds Simple uorescent measurement after cell lysis allows determining cell attachment and p liferation on synthetic polymers Finally CHO cells producing human recombinant collagen I and elastin were generated We showed that both proteins are expressed and secreted by CHO DG44 cells 2 Materials and Methods 2
